## CAPSAICIN RECEPTOR LIGANDS

## Field of the Invention

This invention relates compounds that bind with high  
5 selectivity and high affinity to Vanilloid Receptors,  
especially Type I Vanilloid Receptors, also known as capsaicin  
receptors or VR1 Receptors. In an important aspect the  
invention provides capsaicin receptor, preferably human VR1  
10 receptor, antagonists that are not capsaicin analogs (e.g.,  
they do not contain a phenyl ring with two oxygen atoms bound  
to two adjacent ring carbons), are free of agonist activity,  
and exhibit an unprecedented level of affinity for the VR1  
receptor. In another aspect, the invention provides aryl  
15 piperazines and related compounds that act as VR1 receptor  
ligands. In addition, this invention relates to such VR1  
receptor ligands, high affinity antagonists and pharmaceutical  
compositions comprising such compounds and to the use of such  
compounds in treatment of diseases and other health-related  
20 conditions. Additionally this invention relates to the use of  
aryl piperazines and related compounds as tool for the analysis  
of VR1 receptors and as probes for the quantitative measurement  
and localization of VR1 receptors in cell and tissue samples.

## Background

The sensation of pain can be triggered by any number of  
25 physical or chemical stimuli. In mammals, the peripheral  
terminals of a group of specialized small diameter sensory  
neurons, termed "nociceptors" mediate this response to a  
potentially harmful stimulus.

In efforts to discover better analgesics for the treatment  
30 of both acute and chronic pain, and to develop treatments for  
various neuropathic pain states, considerable research has been

focused on the molecular mechanism of nociception. The response to heat, low extracellular pH (acidity), or capsaicin (the compound responsible for the hotness of hot peppers) is characterized by the persistent activation of nociceptors. It has been shown that both heat and capsaicin are capable of activating dorsal root ganglion and trigeminal ganglion neurons via an influx of cations. Additionally, moderately acidic conditions produce this response and can also potentiate the response of nociceptors to heat and capsaicin.

Capsaicin responses in isolated sensory neurons show dose-dependence and are also evoked by structural analogues of capsaicin that share a common vanilloid moiety. The term vanilloid receptor (VR) was coined to describe the neuronal membrane recognition site for capsaicin and such related irritant compounds. It was postulated that the VR is a nonselective cation channel with a preference for calcium. In 1989, resiniferatoxin (RTX), a natural product of certain *Euphorbia* plants, was recognized as an ultrapotent VR agonist. Specific binding of  $^3\text{H}$  RTX provided the first unequivocal proof for the existence of a vanilloid receptor. The capsaicin response is competitively inhibited (and thereby antagonized) by another capsaicin analog, capsazepine and is also inhibited by the non-selective cation channel blocker ruthenium red. These antagonists bind to VR with no more than moderate affinity (i.e., with  $K_i$  values of no lower than 140  $\mu\text{M}$ ).

Interest in characterizing VRs led to the cloning of a functional rat capsaicin receptor (VR1), from a rat dorsal root ganglion cDNA library. A human version of VR1 has also been described, and the term VR1 is used herein to refer to either or both.

The capsaicin receptor's channel opens in response to elevated temperatures (higher than about 45°C). Capsaicin and related compounds, as well as protons are stimuli that lower the threshold channel opening, so that in the presence of any of these stimuli the capsaicin receptor can be opened even at room temperature.

Opening of the capsaicin receptor channel is followed by the release of inflammatory peptides from neurons expressing the receptor and other nearby neurons, increasing the pain response. After initial activation by capsaicin the capsaicin receptor undergoes a rapid desensitization, possibly via phosphorylation of intracellular sites of the receptor. Capsaicin and related VR1 agonist vanilloid compounds have enjoyed long pharmaceutical use as topical anaesthetics. While such compounds initially cause a strong burning sensation, receptor desensitization provides pain relief.

Localization of the capsaicin receptor in the dorsal root ganglion established this receptor as a leading target for analgesic discovery. Most currently marketed analgesic compounds act centrally, and often have side effects. Analgesic compounds that act peripherally are desirable for treating acute and chronic pain more effectively and with fewer side effects. Thus, compounds that interact with the capsaicin receptors, particularly antagonists of this receptor, which would not elicit the initial painful sensation of currently marketed capsaicin containing compounds, are desirable for the treatment of chronic and acute pain, itch, and urinary incontinence.

#### Description of Related Art

The vanilloid compounds capsaicin and Resiniferatoxin (RTX) act as potent and specific agonists of the capsaicin

receptor. Capsazepine (which contains a phenyl ring with two oxygen atoms bound to two adjacent ring carbons and is therefore a capsaicin analog) acts as a moderate affinity competitive capsaicin receptor antagonist. Iodo-RTX is a  
5 capsaicin analog that has recently been reported to act as a high affinity antagonist. The inorganic dye, Ruthenium red, also antagonizes capsaicin responses of the receptor, albeit as a non-selective cation channel blocker. For an extensive review of vanilloid receptor ligands see Szallasi and Blumberg,  
10 (Pharmacological Reviews (1999) 51(3): 159-211).

#### Summary of the Invention

This invention relates to VR1 receptor ligands, particularly VR1 receptor antagonists, and methods of using VR1 receptor antagonists for the treatment of neuropathic pain,  
15 peripheral-nerve-mediated pain, and pain, inflammatory and broncho-constriction symptoms resulting from exposure to capsacin-receptor-activating stimuli such as capsaicin and tear gas.

In one aspect the invention provides novel chemical  
20 compounds that act as capsaicin receptor modulatory agents, some of which exhibit antagonist potency greater than that of any previously described VR1 receptor antagonist. Compounds that act as capsaicin receptor antagonists and bind to capsaicin (preferably human VR1) receptors with  $K_i$  values of  
25 less than 100uM, as measured by a capsacin receptor binding assay, such as the assay given by Example 10, or that inhibit capsaicin activity in an assay for determination of capsaicin receptor antagonist effects (Example 11) with  $EC_{50}$  values of less than or equal to 100uM, are referred to herein as potent  
30 capsaicin receptor antagonists; such compounds that bind or antagonize with  $K_i$  or  $EC_{50}$  values of less than or equal to 10uM

are referred to herein as highly potent capsaicin receptor antagonists.

In an additional aspect, the invention provides methods of using the potent capsaicin receptor antagonist compounds of the invention for the treatment of symptoms resulting from exposure to painful capsaicin receptor activating stimuli. In particular, the invention provides methods of treating subjects who have been exposed to capsaicin or have been burnt by heat, light, tear gas, or acid exposure, the methods comprising administering to such subjects an effective amount of a potent capsaicin receptor antagonist, preferably a highly potent (high potency) capsaicin receptor antagonist, so that the subject's symptoms of pain or sensitivity are reduced. Preferred compounds of the invention provide pain relief without loss of consciousness, and preferably without sedation, in such subjects that is equal to or greater than the degree of pain relief that can be provided to such subjects by morphine without loss of consciousness. Highly preferred compounds provide such pain relief while causing only transient (i.e., lasting for no more than one half the time that pain relief lasts) or no sedation (see Example 16 for sedation assay). Subjects or patients referred to herein may be humans or non-human mammals including domestic companion animals (pets) and livestock animals, as discussed more fully below.

In yet another aspect the invention provides methods of treating of neuropathic pain based on the unexpected finding that capsaicin receptor antagonists can alleviate such pain.

This invention also provides aryl piperazines and related compounds that bind with high affinity and high selectivity to capsaicin receptors, including human capsaicin receptors, also known as VR1 receptors.

Thus, the invention provides novel compounds of Formula I, Formula II, Formula III, Formula IV, Formula V, Formula VI, or Formula VII, Formula VIII, Formula IX and Formulae A-F shown below (the "compounds of the invention," hereinafter Formulae I-IX and Formulae A-F), and pharmaceutical compositions comprising compounds of Formulae I-IX and Formulae A-F.

The invention further comprises methods of treating patients suffering from certain diseases or conditions, especially those involving pain or urinary incontinence, with an amount of a compound Formulae I-IX and Formulae A-F that is effective to improve the symptoms (e.g., reduce pain or reduce the frequency of urinary incontinence) of the disease or condition being treated.

Additionally this invention relates to the use of the compounds of the invention as reagents, standards, and probes for measurement, characterization and localization of capsaicin receptors, particularly VR1 receptors (e.g., in cells or tissues).

Accordingly, a broad aspect of the invention is directed to compounds of Formula I:

In one aspect invention relates to diaryl piperazines and related compounds that bind with high affinity to capsaicin receptors, including human capsaicin receptors. Compounds that

5 bind with high affinity for the capsaicin receptor include compounds exhibit  $K_i$  values of less than 10  $\mu\text{M}$ , and preferably exhibit  $K_i$  values of less than 1  $\mu\text{M}$ , more preferably exhibit  $K_i$  values of less than 100 nM, and most preferably exhibit  $K_i$  values of less than 10 nM at the capsaicin receptors. This

10 invention also includes diaryl piperazines that bind with high selectivity to capsaicin receptor. Compounds that exhibit high selectivity for the capsaicin receptor exhibit at least 20-fold, and preferably at least 100-fold greater affinity for the capsaicin receptor than for other cell surface receptors (e.g.,

Without wishing to be bound to any particular theory of operation, it is believed that the interaction of the compounds of Formulae I-IX and Formulae A-F with the capsaicin receptor results in the pharmaceutical utility of these compounds.

5 treating a disorder responsive to capsaicin receptor modulation in the patient.

The present invention also pertains to methods of inhibiting the binding of vanilloid (capsaicin analog) compounds, such as capsaicin, olvanil and RTX, to capsaicin  
10 receptors, which methods involve contacting a compound of the invention with cells expressing capsaicin receptors, wherein the compound is present at a concentration sufficient to inhibit vanilloid binding to capsaicin receptors *in vitro*. The methods of the invention include inhibiting the binding of  
15 vanilloid compounds to capsaicin receptors *in vivo*, e.g., in a patient given an amount of a compound of Formulae I-IX and Formulae A-F that results in and *in vivo* concentration in a body fluid sufficient to inhibit the binding of capsaicin compounds to capsaicin receptors *in vitro*. In one embodiment,  
20 such methods are useful in treating the effects of tear gas, hot pepper or pepper spray exposure. The amount of a compound that would be sufficient to inhibit the binding of a vanilloid compound to the capsaicin receptor may be readily determined via a capsaicin receptor binding assay, such as the assay  
25 described in Example 10 or by an assay of capsaicin receptor antagonism e.g., as in Example 11. The capsaicin receptors used to determine *in vitro* binding may be obtained from a variety of sources, for example from preparations of mammalian dorsal root ganglion (DRG) or from cells expressing cloned rat or human  
30 capsaicin receptors.

The present invention also pertains to methods for altering the signal-transducing activity, particularly the calcium ion conductance, mediated by capsaicin receptors, said method comprising exposing cells expressing such receptors to a solution comprising a compound of the, wherein the compound is present in the solution at a concentration sufficient to specifically alter the calcium conductance activity in response to capsaicin or RTX in vitro in cells expressing capsaicin receptors, preferred cells for this purpose are those that express high levels of capsaicin receptors (i.e., equal to or greater than the number of capsaicin receptors per cell found in rat DRG cells).. This method includes altering the signal-transducing activity of capsaicin receptors *in vivo*. Preferably such alterations are reductions of calcium flux. The amount of a compound that would be sufficient to alter the signal-transducing activity of capsaicin receptors may be determined in vitro via a capsaicin receptor signal transduction assay, such as the calcium mobilization (conductance, flux) assay described in Example 11. The amount of a compound that would be sufficient to alter the calcium conductance activity in response to capsaicin or RTX of capsaicin receptors may also be determined via an assay of capsaicin receptor mediated calcium conductance, such as an assay wherein the binding of capsaicin to a cell surface capsaicin receptor effects changes in the fluorescence of a calcium sensitive dye or in the expression of a calcium sensitive reporter gene.

A compound of the invention, wherein the compound is not addictive.

The capsaicin receptor ligands provided by this invention and labeled derivatives thereof are also useful as standards  
5 and reagents for determining the ability of a compound to bind to the capsaicin receptor and to act as an agonist, antagonist, inverse agonist, mixed agonist/antagonist or the like.

More particularly compounds of the invention may be used for demonstrating the presence of VR1 receptors or other  
10 capsaicin receptors in cell or tissue samples. This may be done by preparing a plurality of matched cell or tissue samples, at least one of which is prepared as an experimental sample and at least one of which is prepared as a control sample. The experimental sample is prepared by contacting  
15 (under conditions that permit binding of capsaicin or RTX to capsaicin receptors within cell and tissue samples) at least one of the matched cell or tissue samples that has not previously been contacted with any compound or salt of the invention with an experimental solution comprising the  
20 detectably-labeled preparation of the selected compound or salt at a first measured molar concentration. The control sample is prepared by in the same manner as the experimental sample and is incubated in a solution that contains the same ingredients as the experimental solution but that also contains an  
25 unlabelled preparation of the same compound or salt of the invention at a molar concentration that is greater than the first measured molar concentration.

The experimental and control samples are then washed (using the same wash conditions) to remove unbound detectably-  
30 labeled compound. The amount of detectably-labeled compound remaining bound to each sample is then measured and the amount

of detectably-labeled compound in the experimental and control samples is compared. A comparison that indicates the detection of a greater amount of detectable label in the at least one washed experimental sample than is detected in any of the at least one washed control samples demonstrates the presence of capsaicin receptors in that experimental sample.

The detectably-labeled compound used in this procedure may be labeled with any detectable label, such as a radioactive label, a biological tag such as biotin (which can be detected by binding to detectably-labeled avidin), an enzyme (e.g., alkaline phosphatase, beta galactosidase, or a like enzyme that can be detected its activity in a colorimetric, luminescent, or like assay) or a directly or indirectly luminescent label. When tissue sections are used in this procedure and the detectably-labeled compound is radiolabeled, the bound, labeled compound may be detected autoradiographically to generate an autoradiogram. When autoradiography is used, the amount of detectable label in an experimental or control sample may be measured by viewing the autoradiograms and comparing the exposure density of matched regions of the autoradiograms.

Labeled derivatives the capsaicin receptor ligands provided by this invention are also useful as radiotracers for positron emission tomography (PET) imaging or for single photon emission computerized tomography (SPECT) to characterize and localize capsaicin receptors in vivo.

#### Definitions

The compounds herein described may have one or more asymmetric centers or planes. Compounds of the present invention containing an asymmetrically substituted atom may be isolated in optically active or racemic forms. It is well known in the art how to prepare optically active forms, such as by

resolution of racemic forms (racemates), by asymmetric synthesis, or by synthesis from optically active starting materials. Resolution of the racemates can be accomplished, for example, by conventional methods such as crystallization in the presence of a resolving agent, or chromatography, using, for example a chiral HPLC column. Many geometric isomers of olefins, C=N double bonds, and the like can also be present in the compounds described herein, and all such stable isomers are contemplated in the present invention. *Cis* and *trans* geometric isomers of the compounds of the present invention are described and may be isolated as a mixture of isomers or as separated isomeric forms. All chiral (enantiomeric and diastereomeric), and racemic forms, as well as all geometric isomeric forms of a structure are intended, unless the specific stereochemistry or isomeric form is specifically indicated.

The term "substituted," as used herein, means that any one or more hydrogens on the designated atom is replaced with a selection from the indicated group, provided that the designated atom's normal valence is not exceeded, and that the substitution results in a stable compound. By way of general example and without limitation, isotopes of hydrogen include tritium and deuterium. Isotopes of carbon include  $^{11}\text{C}$ ,  $^{13}\text{C}$ , and  $^{14}\text{C}$ .

When any variable occurs more than one time in any constituent or formula for a compound, its definition at each occurrence is independent of its definition at every other occurrence. Thus, for example, if a group is shown to be substituted with 0-2  $\text{R}^*$ , then said group may optionally be

substituted with up to two R\* groups and R\* at each occurrence is selected independently from the definition of R\*. Also, combinations of substituents and/or variables are permissible only if such combinations result in stable compounds.

will therefore melt in the rectum to release the drug. Such materials are cocoa butter and polyethylene glycols.

Compounds of general Formulae I-IX and general Formulae A-F may be administered parenterally in a sterile medium. The  
5 drug, depending on the vehicle and concentration used, can either be suspended or dissolved in the vehicle. Advantageously, adjuvants such as local anesthetics, preservatives and buffering agents can be dissolved in the vehicle where desirable.

10 Typical subjects to which compounds of the invention may be administered will be mammals, particularly primates, especially humans. For veterinary applications, a wide variety of subjects will be suitable, e.g. livestock such as cattle, sheep, goats, cows, swine and the like; poultry such as  
15 chickens, ducks, geese, turkeys, and the like; and other domesticated animals particularly pets (companion animals) such as dogs and cats. For diagnostic or research applications, a wide variety of mammals will be suitable subjects including rodents (e.g. mice, rats, hamsters), rabbits, primates, and  
20 swine such as inbred pigs and the like.

For administration to non-human animals, the composition may also be added to the animal feed or drinking water. It will be convenient to formulate these animal feed and drinking water compositions so that the animal takes in an appropriate  
25 quantity of the composition along with its diet. It will also be convenient to present the composition as a premix for addition to the feed or drinking water.

For systemic (as opposed to local or topical) administration, dosage levels of the order of from about  
30 0.01 mg to about 140 mg per kilogram of body weight per day are useful in the treatment of pain, urinary incontinence, or other

of the above-indicated conditions (about 0.05 mg to about 7 g per human patient per day). Preferred systemic doses for preferred high potency compounds of Formulae I-IX and Formulae A-F range from about 0.01 mg to about 50 mg per kilogram of body weight per subject per day, with oral doses generally being about 5-20 fold higher than intravenous doses. The most highly preferred compounds of the invention are orally active (e.g., provide a reduction of pain or a reduction of frequency of urinary incontinence) at doses ranging from 0.05 to 40 mg per kilogram of body weight per subject per day.

The amount of active ingredient that may be combined with the carrier materials to produce a single dosage form will vary depending upon the host treated and the particular mode of administration. Dosage unit forms will generally contain between from about 1 mg to about 500 mg of an active ingredient.

Frequency of dosage may also vary depending on the compound used and the particular disease treated. However, for treatment of most disorders, a dosage regimen (frequency of administration) of 4 times daily or less is preferred. For the treatment of chronic pain or urinary incontinence a dosage regimen of 2 times daily is more preferred and a frequency of administration of once a day is particularly preferred. For the treatment of acute pain a single dose that rapidly reaches effective concentrations is desirable.

It will be understood, however, that the specific dose level for any particular patient will depend upon a variety of factors including the activity of the specific compound employed, the age, body weight, general health, sex, diet, time of administration, route of administration, and rate of

excretion, drug combination and the nature and severity of the particular disease or condition undergoing treatment.

Preferred compounds of the invention will have certain desirable pharmacological properties. For systemic administration such properties include, but are not limited to high oral bioavailability, such that the preferred oral dosages and dosage forms discussed above can provide therapeutically effective levels of the compound *in vivo*, low serum protein binding and low first pass hepatic metabolism. For all types of administration low toxicity, and desirable *in vitro* and *in vivo* half-lives are desired. While penetration of the blood brain barrier for compounds used to treat CNS disorders is necessary, low brain levels of compounds used to treat peripheral disorders (such as urinary incontinence, or chronic or acute pain that does not originate from the CNS) are often preferred.

Laboratory assays may be used to predict these desirable pharmacological properties. The discussion that follows is supplemented by the detailed protocols of Example 16, *infra*. Assays used to predict bioavailability include transport across human intestinal cell monolayers, including Caco-2 cell monolayers. Toxicity to cultured hepatocytes may be used to predict compound toxicity, with non-toxic compounds being preferred. Penetration of the blood brain barrier of a compound in humans may be predicted from the brain levels of the compound in laboratory animals given the compound, e.g., intravenously.

Percentage of serum protein binding may be predicted from albumin binding assays. Examples of such assays are described in a review by Oravcová, et al. (Journal of Chromatography B (1996) volume 677, pages 1-27). Preferred compounds exhibit reversible serum protein binding. Preferably this binding is

less than 99%, more preferably less than 95%, even more preferably less than 90%, and most preferably less than 80%.

Frequency of administration is generally inversely proportional to the *in vivo* half-life of a compound. *In vivo* half-lives of compounds may be predicted from the results of assays, e.g., *in vitro* assays of microsomal half-life as described by Kuhnz and Gieschen (*Drug Metabolism and Disposition*, 1998, volume 26, pages 1120-1127). Preferred half-lives are those allowing for a preferred frequency of administration.

Example 10Capsaicin Receptor Binding Assay

The following assay is a standard assay of capsaicin receptor binding that may be used to determine the binding affinity of compounds for the capsaicin (VR1) receptor.

Materials. [<sup>3</sup>H]Resiniferatoxin (RTX; 37 Ci/mmol) was synthesized by and obtained from the Chemical Synthesis and Analysis Laboratory, National Cancer Institute-Frederick Cancer Research and Development Center, Frederick, MD. [<sup>3</sup>H] RTX may also be obtained from commercial vendors, e.g., Amersham Pharmacia Biotech, Inc. 800 Centennial Avenue, P.O. Box 1327, Piscataway, NJ 08855 (code TRK 1069). Nonradioactive RTX may be purchased from Alexis Corp. (San Diego, CA) and capsazepine from RBI (Natick, MA).

Molecular Biology

A cDNA encoding the full length human capsaicin receptor (SEQ ID NO:1 or SEQ ID NO:2) is subcloned in the appropriate orientation for expression into an expression vector such as pcDNA3.1 (Invitrogen, Carlsbad, CA) or pUHG102-3 (Clontech, Palo Alto, CA) for recombinant expression in mammalian cells.

Cell Culture. Human embryonic kidney (HEK293) cells are transfected with a pcDNA3.1 expression construct encoding the full length human capsaicin receptor (i.e. containing either the nucleotide sequence of SEQ ID NO:1 and SEQ ID NO:2) using standard methods. These transfected cells are selected for two weeks in media containing G418 (400 ug/ml) and then maintained as a pool of stably transfected cells.

pUHG102 VR1 expression plasmids are transfected into Chinese Hamster Ovary (CHO) cells containing the pTet Off Regulator plasmid (Clontech). In these cells, expression of the pUHG plasmid is repressed in the presence of tetracycline but is induced upon removal of the antibiotic. Stable clones are isolated in culture medium containing puromycin (10 ug/ml) and maintained in medium supplemented with tetracycline (1 ug/ml). Cells utilized for assays are grown in culture medium without antibiotic for 48-72 hours prior to use. For radioligand binding experiments, cells are seeded in T175 cell culture flasks in media without antibiotics and grown to approximately 90% confluency. The flasks are then washed with PBS and harvested in PBS containing 5 mM EDTA. The cells are pelleted by gentle centrifugation and stored at -80°C until assayed.

#### Membrane Preparations

Previously frozen cells are disrupted with the aid of a tissue homogenizer in ice-cold HEPES homogenization buffer (5mM KCl, 5.8mM NaCl, 0.75mM CaCl<sub>2</sub>, 2mM MgCl<sub>2</sub>, 320 mM sucrose, and 10 mM HEPES pH 7.4). Tissue homogenates are first centrifuged for 10 min at 1000 x g (4 °C) to remove the nuclear fraction and debris and then the supernatant from the first centrifugation is further centrifuged for 30 min at 35,000 x g (4°C) to obtain a partially purified membrane fraction. Membranes are resuspended in the HEPES homogenization buffer prior to being

assayed. An aliquot of this membrane homogenate is used to determine protein concentration via the Bradford method (BIO-RAD Protein Assay Kit, #500-0001, BIO-RAD, Hercules, CA).

#### Radioligand Binding

- 5 Binding studies with [<sup>3</sup>H]RTX are carried out essentially according to a published protocol (Szallasi and Blumberg, 1992, *J. Pharmacol. Exp. Ter.* 262: 883-888) in which non-specific RTX binding is reduced by adding bovine alpha<sub>1</sub> acid glycoprotein (100 ug per tube) after the binding reaction has been
- 10 terminated. The homogenate is centrifuged as before and resuspended to a protein concentration of 333ug/ml in homogenization buffer. Binding assay mixtures were set up on ice and contained [<sup>3</sup>H]RTX (specific activity 2200 mCi/ml), 2 ul non-radioactive ligands test compound, 0.25 mg/ml bovine serum
- 15 albumin (Cohn fraction V), and  $5 \times 10^4$  -  $1 \times 10^5$  VR1-transfected cells. The final volume was adjusted to 500 ul (competition binding assays) or 1,000 ul (saturation binding assays) with the ice-cold HEPES homogenization buffer solution (pH 7.4) described above. Non-specific binding was defined as that
- 20 occurring in the presence of 1 uM non-radioactive RTX. For saturation binding, [<sup>3</sup>H]RTX was added in the concentration range of 7 - 1,000 pM, using 1 to 2 dilutions. Typically 11 concentration points are collected per saturation binding curve.
- 25 Competition binding assays were performed in the presence of 60 pM [<sup>3</sup>H]RTX and various concentrations of competing ligands. The binding reactions are initiated by transferring the assay mixtures into a 37°C water bath and are terminated following a 60 min incubation period by cooling the tubes on
- 30 ice. Membrane-bound RTX is separated from free, as well as any alpha<sub>1</sub>-acid glycoprotein-bound RTX, by filtration onto WALLAC

glass fiber filters (PERKIN-ELMER, Gaithersburg, MD) which are pre-soaked with 1.0% PEI (polyethyleneimine) for 2 hours prior to use. Filters are allowed to dry overnight then counted in a WALLAC 1205 BETA PLATE counter after addition of WALLAC BETA SCINT scintillation fluid.

Equilibrium binding parameters were determined by fitting the allosteric Hill equation to the measured values with the aid of the computer program FIT P (Biosoft, Ferguson, MO) as described previously (Szallasi, et al. (1993) *J. Pharmacol. Exp. Ther.* 266:678 -683)).

Though compounds exhibiting  $K_i$  values for capsaicin receptors of greater than 1  $\mu\text{M}$  are generally less preferred as pharmaceutical agents, useful compounds of the invention exhibit  $K_i$  values for capsaicin receptors of less than 4  $\mu\text{M}$ , more preferred compounds exhibit  $K_i$  values of less than 1  $\mu\text{M}$ , even more preferred compounds exhibit  $K_i$  values of less than 100 nM, more highly preferred compounds exhibit  $K_i$  values of less than 50 nM, even more highly preferred compounds exhibit  $K_i$  values of less than 25 nM and the most preferred compounds of the invention yield  $K_i$  values of less than or about equal to 10 nM in this assay.

#### Example 11

##### Calcium Mobilization Assay

The following assay can be used to monitor the response of cells capsaicin receptors to capsaicin and other vanilloid ligands of the capsaicin receptor. The assay can also be used to determine if test compounds act as agonists or antagonists of capsaicin receptors.

Cells transfected with expression plasmids (as described in Example 10) and thereby expressing the human capsaicin receptor are seeded and grown to 70-90% confluency in FALCON

black-walled, clear-bottomed 96-well plates (#3904, BECTON-DICKINSON, Franklin Lakes, NJ). The culture media are emptied from the 96 well plates and FLUO-3 AM calcium sensitive dye (Molecular Probes, Eugene, OR) is added to each well (dye solution: 1 mg FLUO-3 AM, 440 uL DMSO and 440 ul 20% pluronic acid in DMSO, diluted 1:4, 50 ul diluted solution per well). Plates are covered with aluminum foil and incubated at 37 C for 1-2 hours in an environment containing 5% CO<sub>2</sub>. After the incubation the dye is emptied from the plates, and the cells are washed once with Krebs-Ringer HEPES (KRH) buffer (25 mM HEPES, 5 mM KCl, 0.96 mM NaH<sub>2</sub>PO<sub>4</sub>, 1 mM MgSO<sub>4</sub>, 2 mM CaCl<sub>2</sub>, 5 mM glucose, 1 mM probenecid, pH 7.4), and resuspended in KRH buffer.

Agonist (e.g., olvanil, capsaicin, or RTX)-induced calcium mobilization is monitored using either FLUOROSKAN ASCENT (Labsystems, Franklin, MA) or FLIPR (fluorometric imaging plate reader system, Molecular Devices, Sunnyvale, CA) instruments. Similarly, varying concentrations of the antagonists ruthenium red or capsazepine are added to cells concurrently with agonist (e.g., 25-50 nM capsaicin). For agonist-induced calcium responses, data obtained between 30 and 60 seconds after agonist application are used to generate the EC<sub>50</sub> values. KALEIDAGRAPH software (Synergy Software, Reading, PA) was utilized to fit the data to the equation:

$$y = a * (1 / (1 + (b/x)^c))$$

to determine the EC<sub>50</sub> for the response. In this equation, y is the maximum fluorescence signal, x is the concentration of the agonist or antagonist, a is the E<sub>max</sub>, b corresponds to the EC<sub>50</sub> or IC<sub>50</sub> value, and finally, c is the Hill coefficient.

### Assay for Determination of Capsaicin Receptor Antagonist Effects

In order to measure the ability of a test compound to antagonize (inhibit) the response of cells expressing capsaicin receptors to capsaicin or other vanilloid agonist, the  $EC_{50}$  of capsaicin is first determined.

5       An additional 20  $\mu$ l of KRH buffer and 1  $\mu$ l DMSO is added to each well of cells, prepared as described above. 100  $\mu$ l capsaicin in KRH buffer is automatically transferred by the FLIPR instrument to each well. An 8-point concentration response curve, with final capsaicin concentrations of 1 nM to  
10   3  $\mu$ M, is used to determine capsaicin  $EC_{50}$ .

Test compounds are dissolved in DMSO, diluted in 20  $\mu$ l KRH buffer so that the final concentration of test compounds in the assay well is between 1  $\mu$ M and 5  $\mu$ M, and added to cells prepared as described above. The 96 well plates containing  
15   prepared cells and test compounds are incubated in the dark, at room temperature for 0.5 - 6 hours. It is important that the incubation not continue beyond 6 hours. Just prior to determining the fluorescence response, 100  $\mu$ l capsaicin in KRH buffer at twice the  $EC_{50}$  concentration determined from the  
20   concentration response curve is automatically added by the FLIPR instrument to each well of the 96 well plate for a final sample volume of 200  $\mu$ l and a final capsaicin concentration equal to the  $EC_{50}$ . The final concentration of test compounds in the assay wells is between 1  $\mu$ M and 5  $\mu$ M. Typically cells exposed to one  
25    $EC_{50}$  of capsaicin exhibit a fluorescence response of about 10,000 Relative Fluorescence Units. Antagonists of the capsaicin receptor decrease this response by about 20%, preferably by about 50%, and most preferably by at least 80% as compared to matched control. The concentration of antagonist  
30   required to provide a 50% decrease is the  $EC_{50}$  for the antagonist (also referred to as the  $IC_{50}$ ).

Equilibrium binding parameters may be determined as described in Example 10.

Assay for Determination of Capsaicin Receptor Agonist Effects

The ability of a compound to act as an agonist of the  
5 capsaicin receptor may be determined by measuring the  
fluorescence response of cells expressing capsaicin receptors,  
using the methods described above, in the absence of capsaicin,  
RTX, or other known capsaicin receptor agonists. Compounds  
that cause cells to exhibit fluorescence above background are  
10 capsaicin receptor agonists. Highly preferred compounds of the  
invention are antagonists that are essentially free of agonist  
activity as demonstrated by the absence of detectable agonist  
activity in such an assay at compound concentrations below 4  
nM, more preferably at concentrations below 10 uM and most  
15 preferably at concentrations less than or equal to 100 uM.

Example 12

NPY Y5 receptor binding assay

The following assay is a standard assay for NPY Y5  
20 (neuropeptide Y receptor 5) receptor binding that may be used  
to determine the affinity of compounds for the NPY Y5 receptor.  
Expression of a recombinant human Y5 receptor in cultured cells  
and receptor binding assays using of membranes prepared from  
such cells has been described previously, e.g. in US patent no.  
25 5,602,024 at columns 17-20. US patent no. 5,602,024 is hereby  
incorporated by reference for its teachings regarding a  
recombinant human Y5 receptor, expression of this receptor in  
cultured cells, and receptor binding assays using membranes  
prepared from such cells.

30

### Cell Culture

Baculovirus-infected Sf9 cells expressing recombinant human NPY Y5 receptors are harvested at 48 hrs.

### Membrane preparation

- 5 Sf9 cell pellets are resuspended in lysis buffer (20mM Tris-HCL, 5mM EDTA, 0.5 ug/ml leupeptin, 2 ug/ml Aprotinin, 200 uM PMSF, pH 7.4) and homogenized using a POLYTRON homogenizer (setting 3 for 25-30 seconds). The homogenate was centrifuged (536 x g/ 10 minutes/ 4°C) to pellet the nuclei. The
- 10 supernatant containing isolated membranes are decanted to a clean centrifuge tube, centrifuged (48,000 x g/ 30 minutes, 4°C) and resuspended in 30 ml homogenization buffer. This centrifugation and resuspension step is repeated twice. The final pellet is resuspended in ice cold Dulbecco's PBS
- 15 containing 5 mM EDTA and stored in aliquots at -80 °C until needed. The protein concentration of the resulting membrane preparation is measured using the Bradford Protein assay, as described in Example 3. By this measure, a 1-liter culture of cells typically yields 100-125 mg of total membrane protein.
- 20 Thawed Sf9 membranes are washed with PBS and resuspended by Dounce homogenization (tight pestle) in binding buffer (50 mM Tris-HCl, 5 mM KCl, 120 mM NaCl, 2 mM CaCl<sub>2</sub>, 0.1% BSA, pH 7.4).

- For competition binding analysis, membranes (10-25 ug) in
- 25 150 ul binding buffer are added to polypropylene tubes or 96-well deepwell plates containing [<sup>125</sup>I]PY (porcine, NEN, Boston, MA)/GTP. Final concentration of [<sup>125</sup>I]PY is 30-35pM/assay well; final concentration of GTP is 100uM/well. Nonspecific binding is determined in the presence of 1 uM NPY (human,
- 30 American Peptide Co., Sunnyvale, CA) and accounts for less than 10% of total binding. Test compounds at a concentration of 1-

4uM in 2ul DMSO are added to the assay mixtures. Final assay volume is 250 ul. For competition analysis test compounds are added at concentrations ranging from  $10^{-12}$  to  $10^{-6}$  M. Typically 11 concentration points are collected per saturation binding curve. Following a 2-hour incubation at room temperature, the assay reactions are terminated by rapid vacuum filtration. Samples are filtered over presoaked (in polyethyleneimine for 2 hours prior to use) GF/C WHATMAN filters and rinsed 2 times with 5 mls cold binding buffer without BSA. Remaining bound radioactivity is quantified by gamma counting.  $K_i$  values may be determined by the method described in Example 10.

Preferred compounds of the invention exhibit 10-fold greater affinity for the capsaicin receptor than for the chimeric NPY Y5 receptor, more preferred compounds of the invention also exhibit 100-fold greater affinity for the capsaicin receptor than for the chimeric NPY Y5 receptor, and still more preferred compounds of the invention also exhibit 1000-fold greater affinity for the capsaicin receptor than for the chimeric NPY Y5 receptor. Most highly preferred compounds of the invention do not exhibit detectable binding at the NPY 5 receptor.

##### Preparation of radiolabeled probe compounds of the invention

The compounds of the invention are prepared as radiolabeled probes by carrying out their synthesis using precursors comprising at least one atom that is a radioisotope. The radioisotope is preferably selected from of at least one of carbon (preferably  $^{14}\text{C}$ ), hydrogen (preferably  $^3\text{H}$ ), sulfur (preferably  $^{35}\text{S}$ ), or iodine (preferably  $^{125}\text{I}$ ). Such radiolabeled probes are conveniently synthesized by a radioisotope supplier specializing in custom synthesis of radiolabeled probe

compounds. Such suppliers include Amersham Corporation, Arlington Heights, IL; Cambridge Isotope Laboratories, Inc. Andover, MA; SRI International, Menlo Park, CA; Wizard Laboratories, West Sacramento, CA; ChemSyn Laboratories, Lexena, KS; American Radiolabeled Chemicals, Inc., St. Louis, MO; and Moravsek Biochemicals Inc., Brea, CA.

Tritium labeled probe compounds are also conveniently prepared catalytically via platinum-catalyzed exchange in tritiated acetic acid, acid-catalyzed exchange in tritiated trifluoroacetic acid, or heterogeneous-catalyzed exchange with tritium gas. Such preparations are also conveniently carried out as a custom radiolabeling by any of the suppliers listed in the preceding paragraph using the compound of the invention as substrate. In addition, certain precursors may be subjected to tritium-halogen exchange with tritium gas, tritium gas reduction of unsaturated bonds, or reduction using sodium borotritide, as appropriate.

5 Example 15Receptor autoradiography

Receptor autoradiography (receptor mapping) is carried out in vitro as described by Kuhar in sections 8.1.1 to 8.1.9 of

Current Protocols in Pharmacology (1998) John Wiley & Sons, New York, using radiolabeled compounds of the invention prepared as described in the preceding Example.

5 Example 16

Additional Aspects of Preferred Compounds of the Invention

The most preferred compounds of the invention are suitable for pharmaceutical use in treating human patients.

Accordingly, such preferred compounds are non-toxic. They do  
10 not exhibit single or multiple dose acute or long-term toxicity, mutagenicity (e.g., as determined in a bacterial reverse mutation assay such as an Ames test), teratogenicity, tumorigenicity, or the like, and rarely trigger adverse effects (side effects) when administered at therapeutically effective  
15 dosages.

Preferably, administration of such preferred compounds of the invention at certain doses (i.e., doses yielding therapeutically effective *in vivo* concentrations or preferably doses of 0.01, 0.05, 0.1, 0.5, 1, 5, 10, 40, or 50 mg/kg  
20 administered parenterally or preferably orally) does not result in prolongation of heart QT intervals (i.e., as determined by electrocardiography, e.g., in guinea pigs, minipigs or dogs). When administered daily for 5 or preferably ten days, such doses of such preferred compounds also do not  
25 cause liver enlargement resulting in an increase of liver to body weight ratio of more than 100%, preferably not more than 75% and more preferably not more than 50% over matched controls in laboratory rodents (e.g., mice or rats). In another aspect such doses of such preferred compounds also preferably do not  
30 cause liver enlargement resulting in an increase of liver to body weight ratio of more than 50%, preferably preferably not

more than 25%, and more preferably not more than 10% over matched untreated controls in dogs or other non-rodent mammals.

In yet another aspect such doses of such preferred compounds also preferably do not promote the release of liver enzymes (e.g., ALT, LDH, or AST) from hepatocytes *in vivo*. Preferably such doses do not elevate serum levels of such enzymes by more than 100%, preferably not by more than 75% and more preferably not by more than 50% over matched untreated controls *in vivo* in laboratory rodents. Similarly, concentrations (in culture media or other such solutions that are contacted and incubated with cells *in vitro*) equivalent to two, fold, preferably five-fold, and most preferably ten-fold the minimum *in vivo* therapeutic concentration do not cause release of any of such liver enzymes from hepatocytes *in vitro* into culture medium above baseline levels seen in media from untreated cells.

Because side effects are often due to undesirable receptor activation or antagonism, preferred compounds of the invention exert their receptor-modulatory effects with high selectivity. This means that they do not bind to certain other receptors (other than capsaicin receptors) with high affinity, but rather only bind to, activate, or inhibit the activity of such other receptors with affinity constants of greater than 100 nanomolar, preferably greater than 1 micromolar ( $\mu\text{M}$ ), more preferably greater than 10  $\mu\text{M}$  and most preferably greater than 100  $\mu\text{M}$ . Such receptors preferably are selected from the group including ion channel receptors, including sodium ion channel receptors, neurotransmitter receptors such as alpha- and beta-adrenergic receptors, muscarinic receptors (particularly m1, m2, and m3 receptors), dopamine receptors, and metabotropic glutamate receptors; and also include histamine receptors and

cytokine receptors, e.g., interleukin receptors, particularly IL-8 receptors. The group of other receptors to which preferred compounds do not bind with high affinity also includes GABA<sub>A</sub> receptors, bioactive peptide receptors (including  
5 NPY and VIP receptors), neurokinin receptors, bradykinin receptors (e.g., BK1 receptors and BK2 receptors), and hormone receptors (including androgen receptors, thyrotropin releasing hormone receptors and melanocyte-concentrating hormone receptors).

10

Example 16aSodium Ion Channel and Anti-Androgen Activity Criteria

Preferred compounds of the invention do not exhibit significant activity as sodium ion channel blockers, exhibiting  
15 less than 15 percent inhibition, and more preferably less than 10 percent inhibition, of sodium channel specific ligand (e.g., batrachotoxin, tetrodotoxin, or saxitoxin) binding when present at a concentration of 4 uM or less.

Preferred compounds of the invention do not exhibit  
20 significant androgen bioactivity, more preferably they do not exhibit significant androgen antagonist activity, e.g., *in vivo*, in a Hersherberger assay, or *in vitro*, in an assay such as that described by Nellesmann et al., *Toxicology* 2001, 163(1):29-38. Preferred compounds of the invention exhibit less than a  
25 15% inhibition, more preferably less than a 10%, and most preferably less than 5% inhibition of androgen receptor activation in this *in vitro* assay when present at concentrations of 4 uM or less.

By significant activity is meant results varying from  
30 control at the  $p < 0.1$  level or more preferably at the  $p < 0.05$

level of significance as measured using a standard parametric assay of statistical significance such as a student's T test.

5 Microsomal in vitro half-life

Compound half-life values ( $t_{1/2}$  values) may be determined via the following standard liver microsomal half-life assay. Pooled Human liver microsomes are obtained from XenoTech LLC, 3800 Cambridge St., Kansas City, Kansas 66103 (catalog #

- 10 H0610). Such liver microsomes may also be obtained, e.g., from In Vitro Technologies, Baltimore, MD 21227, or from Tissue Transformation Technologies, Edison, NJ 08837. Reactions are performed as follows:

15 Reagents:

Phosphate buffer: 19 mL 0.1 M  $\text{NaH}_2\text{PO}_4$ , 81 mL 0.1  $\text{Na}_2\text{HPO}_4$ , adjusted to pH 7.4 with  $\text{H}_3\text{PO}_4$ .

CoFactor Mixture: 16.2 mg NADP, 45.4 mg Glucose-6-phosphate in 4 mL 100 mM  $\text{MgCl}_2$ .

- 20 Glucose-6-phosphate dehydrogenase: 214.3 ul glucose-6-phosphate dehydrogenase suspension (Boehringer-Manheim catalog no. 0737224, distributed by Roche Molecular Biochemicals, Indianapolis, IN 46250) is diluted into 1285.7 ul distilled water.

- 25 Starting Reaction Mixture: 3 mL CoFactor Mixture, 1.2 mL Glucose-6-phosphate dehydrogenase.

Reaction:

- 6 test reactions are prepared, each containing 25 ul  
30 microsomes, 5 ul of a 100 uM solution of test compound, and 399 ul 0.1 M phosphate buffer. A seventh reaction is prepared as a

positive control containing 25 ul microsomes, 399 ul 0.1 M phosphate buffer, and 5 ul of a 100 uM solution of a compound with known metabolic properties (e.g. DIAZEPAM or CLOZEPINE). Reactions are preincubated at 39°C for 10 minutes. 71 ul

- 5 Starting Reaction Mixture is added to 5 of the 6 test reactions and to the positive control, 71 ul 100 mM MgCl<sub>2</sub> is added to the sixth test reaction, which is used as a negative control. At each time point (0, 1, 3, 5, and 10 minutes) 75 ul of each reaction mix is pipetted into a well of a 96-well deep-well
- 10 plate containing 75 ul ice-cold acetonitrile. Samples are vortexed and centrifuged 10 minutes at 3500 rpm (Sorval T 6000D centrifuge, H1000B rotor). 75 ul of supernatant from each reaction is transferred to a well of a 96-well plate containing 150 ul of a 0.5 uM solution of a compound with a known LCMS
- 15 profile (internal standard) per well. LCMS analysis of each sample is carried out and the amount of unmetabolized test compound is measured as AUC, compound concentration vs time is plotted, and the  $t_{1/2}$  value of the test compound is extrapolated.

- 20 Preferred compounds of the invention exhibit *in vitro*  $t_{1/2}$  values of greater than 10 minutes and less than 4 hours. Most preferred compounds of the invention exhibit *in vitro* half-life values of between 30 minutes and 1 hour in human liver microsomes.

#### MDCK Toxicity Assay

- Compounds causing acute cytotoxicity will produce a substantial decrease of ATP production by Madin Darby canine
- 30 kidney (MDCK) cells in the following assay. Preferred compounds of the invention will not.

MDCK cells, ATCC no. CCL-34 (American Type Culture Collection, Manassas, VA) are maintained in sterile conditions following the instructions in the ATCC production information sheet. The PACKARD, (Meriden, CT) ATP-LITE-M Luminescent ATP  
5 detection kit, product no. 6016941, allows measurement ATP production in MDCK cells.

Prior to assay 1 ul of test compound or control sample is pipetted into PACKARD (Meriden, CT) clear bottom 96-well plates. Test compounds and control samples are diluted in DMSO  
10 to give final concentration in the assay of 10 micromolar, 100 micromolar, or 200 micromolar. Control samples are drug or other compounds having known toxicity properties.

Confluent MDCK cells are trypsinized, harvested, and diluted to a concentration of  $0.1 \times 10^6$  cells/ ml with warm  
15 (37°C) VITACELL Minimum Essential Medium Eagle (ATCC catalog # 30-2003). 100ul of cells in medium is pipetted into each of all but five wells of each 96-well plate. Warm medium without cells (100ul) is pipetted in the remaining five wells of each plate to provide standard curve control wells. These wells, to  
20 which no cells are added, are used to determine the standard curve. The plates are then incubated at 37°C under 95% O<sub>2</sub>, 5% CO<sub>2</sub> for 2 hours with constant shaking. After incubation, 50 ul of mammalian cell lysis solution is added per well, the wells are covered with PACKARD TOPSEAL stickers, and plates are  
25 shaken at approximately 700 rpm on a suitable shaker for 2 minutes.

During the incubation, PACKARD ATP LITE-M reagents are allowed to equilibrate to room temperature. Once equilibrated the lyophilized substrate solution is reconstituted in 5.5 mls  
30 of substrate buffer solution (from kit). Lyophilized ATP standard solution is reconstituted in deionized water to give a

10 mM stock. For the five control wells, 10 ul of serially diluted PACKARD standard is added to each of the five standard curve control wells to yield a final concentration in each subsequent well of 200 nM, 100 nM, 50 nM, 25 nM, and 12.5 nM.

- 5        PACKARD substrate solution (50 ul) is added to all wells. Wells are covered with PACKARD TOPSEAL stickers, and plates are shaken at approximately 700 rpm on a suitable shaker for 2 minutes. A white PACKARD sticker is attached to the bottom of each plate and samples are dark adapted by wrapping plates in  
10 foil and placing in the dark for 10 minutes. Luminescence is then measured at 22°C using a luminescence counter, e.g. PACKARD TOPCOUNT Microplate Scintillation and Luminescence Counter or TECAN SPECTRAFLUOR PLUS.

- Luminescence values at each drug concentration are  
15 compared to the values computed from the standard curve for that concentration. Preferred test compounds exhibit luminescence values 80% or more of the standard, or preferably 90 % or more of the standard, when a 10 micromolar (uM) concentration of the test compound is used. When a 100 uM  
20 concentration of the test compound is used, preferred test compounds exhibit luminescence values 50% or more of the standard, or more preferably 80% or more of the standard. Luminescence values less than 50% of the standard indicate a substantial decrease of ATP production.

Animal Models for Determining Pain Relief and Sedation

- The following experimental protocols can be used to determine the degree of pain relief and sedation provided by  
30 compounds of the invention, e.g., in comparison to pain relief and sedation provided by morphine or pain relief by ibuprofen.

Example 18aCFA arthritis model

Male SD rats are injected with 200 µl of CFA (0.1mg heat  
5 killed and dried *M. tuberculosis*/ml) in the hind paw (100 µl on  
the dorsal and 100 µl on the plantar surface of the paw)  
essentially as described by Bertorelli R, Corradini L, Rafiq K,  
Tupper J, Calo G, Ongini E., *Br J Pharmacol*. 1999 128(6):1252-8  
and by Stein C, Millan MJ, Herz A. *Pharmacol Biochem Behav*.  
10 1988 31(2):455-51.

Rats are tested for thermal (as described by Hargreaves K,  
Dubner R, Brown F, Flores C, Joris J. *Pain*. 1988 32(1):77-88)  
and mechanical (as described by Tal M, Eliav E. *Pain*. 1996  
Mar;64(3):511-8) sensitivities on days 5, 6, and 7. Baseline  
15 data should be obtained for each animal prior to CFA injection.

On day 7, animals are treated orally with a compound of  
the invention, morphine or vehicle (2% vitamin E-TPGS) 1 hour  
prior to testing. Note: an oral dose of 5mg/kg morphine has  
sedative effects.

20 Results are conveniently expressed as % of Maximum  
Potential Efficacy (MPE). 0% MPE is defined as analgesic effect  
of vehicle, 100% MPE is defined as an animal's return to  
baseline level of thermal or mechanical sensitivity.

25 Example 18bMechanical Allodynia

This assay determines the effectiveness of compounds of  
Formulae I-IX and Formulae A-F in relieving at least one of the  
symptoms in an *in vivo* model of pain produced by spinal nerve  
30 ligation, namely mechanical allodynia.

Tactile allodynia is induced in rats using the procedures

described by Bennet and Xie, Pain 1988, 33:87-107. Rats are anesthetized, e.g., with an intraperitoneal dose of pentobarbital sodium (65 mg/kg) with additional doses of anesthetic given as needed. The lateral aspect of each rat's hind limb is shaved and disinfected. Using aseptic technique, an incision is made on the lateral aspect of the hind limb at the mid-thigh level. The biceps femoris is bluntly dissected to expose the sciatic nerve. On one hind limb of each rat, four loosely tied ligatures are made around the sciatic nerve approximately 1-2 millimeters apart. On the other side of each rat, an identical dissection is performed except that the sciatic nerve is not ligated. The muscle is closed with a continuous suture pattern, and the skin is closed with wound clips or sutures.

Mechanical sensitivity is assessed using a procedure described by Chaplan et al. J. Neurosci. Methods 1994, 53:55-63. A series of Von Frey filaments of varying rigidity strength (typically eight filaments in the series) are applied to the plantar surface of the hind paw ipsilateral to the ligations with just enough force to bend the filament. The filaments are held in this position for no more than three seconds or until a positive allodynic response is displayed by the rat. A positive allodynic response consists of lifting the affected paw followed immediately by licking or shaking of the paw. The order and frequency with which the individual filaments are applied are determined by using Dixon up-down method. Testing is initiated with the middle hair of the series with subsequent filaments being applied in consecutive fashion, ascending or descending, depending on whether a negative or positive response, respectively, is obtained with the initial filament.

Certain preferred compounds of Formulae I-IX and Formulae

A-F are effective in reversing mechanical allodynia-like symptoms (i.e., rats treated with effective amounts of such compounds will require stimulation with a Von Frey filament of higher rigidity strength to provoke a positive allodynic response as compared to control untreated or vehicle treated rats) when tested by this method.

##### Cold Allodynia

- 10 This assay determines the effectiveness of compounds in relieving one of the symptoms of neuropathic pain produced by unilateral mononeuropathy, namely cold allodynia.

Unilateral mononeuropathy is produced in rats using the Chronic Constriction Injury model performed essentially as described by Bennet and Xie, Pain 1988, 33:87-107. Rats are anesthetized. The lateral aspect of each rat's hind limb is shaved and disinfected. Using aseptic technique, an incision is made on the lateral aspect of the hind limb at the mid-thigh level. The biceps femoris is bluntly dissected to expose the sciatic nerve. On one hind limb of each rat, four loosely tied ligatures are made around the sciatic nerve approximately 1-2 millimeters apart. On the other side of each rat, an identical dissection is performed except that the sciatic nerve is not ligated. The muscle is closed with a continuous suture pattern, and the skin is closed with wound clips or sutures.

Rats demonstrating unilateral mononeuropathy are assessed for acute and chronic cold allodynia sensitivity. Each rat is placed individually into a chamber with a metal plate about 6 cm from the bottom. This chamber is filled with ice water to a depth of about 2.5 cm above the metal plate, with the temperature of the bath maintained at about zero to four

degrees C throughout the experiment. A timer is started, and the rat's response latency is measured to the nearest tenth of a second. A "response" is defined as a rapid withdrawal of the ligated hindpaw completely out of the water while the animal is stationary and not pivoting. An exaggerated limp while the animal is walking is not scored as a response. Maximum immersion time is 20 seconds with a 20-minute interval between trials. The screening criteria are 1) the average of two trials is less than or equal to 13 seconds, and 2) there is consistency across the two trial scores. Animals are screened for hypersensitivity to cold on post-surgery days 4 through 10, and selected for inclusion in drug-response studies based on the criteria described above. The pre-dose screening values are used as the animal's baseline cold allodynia scores. For acute studies, the animals are tested for cold allodynia at 1, 3, and sometimes 5 hours post-dose. Although this acute cold allodynia assay is generally less preferred for demonstrating efficacy of compounds of the invention, when tested in this assay, certain preferred compounds of Formulae I-IX and Formulae A-F demonstrate anti-allodynic effects (increases in response latency) at doses of less than 50 mg/kg.

#### Example 18d

##### 25 Mechanical Hyperalgesia

This assay determines the effectiveness of compounds in relieving one of the symptoms of neuropathic pain produced by unilateral mononeuropathy, namely mechanical hyperalgesia.

A chronic constriction injury is produced by loosely ligating the right common sciatic nerve as described by Bennet and Xie, Pain 1988, 33:87-107. The left common sciatic nerve is

visualized, but not manipulated to produce sham conditions.

The rats having a chronic constriction injury are assessed for mechanical hyperalgesia to a pin-prick stimulus as described by Koch et al. Analgesia 1996, 2(3), 157-164. Rats  
5 are placed in individual compartments of a cage with a warmed, perforated metal floor. Hindpaw withdrawal duration is measured after a mild pinprick to the plantar surface of the ligated and sham hindpaws.

Preferred compounds of the invention produce a reduction  
10 of mechanical hyperalgesia (i.e., a reduction in the duration of hindpaw withdrawal) elicited by a pin-prick stimulus in rats with a chronic constriction injury at doses of 50 mg/kg or less when tested by this method.

15 Example 18e

Thermal Hyperalgesia

This assay determines the effectiveness of compounds in relieving one of the symptoms of neuropathic pain produced by unilateral mononeuropathy, namely thermal hyperalgesia.

20 Rats having had surgery as described in Example 18d are assessed for thermal hyperalgesia sensitivity at least 10 days post-surgery. The rats are placed beneath inverted cages upon an elevated glass platform and a radiant heat source beneath the glass is aimed at the plantar hindpaw.

25 The duration of time before the hindpaw is withdrawn from the floor is measured to the nearest tenth of a second. The cutoff time for the heat stimulus is 20 seconds, and the light is calibrated such that this stimulus duration does not burn or blister the skin. Preferably about four latency measurements  
30 are taken for each hindpaw in each test session, alternating left and right hindpaws, with 5-minute intervals between tests.

The times to withdrawal of each side are averaged and a difference score is obtained.

Preferred compounds of the invention produce an increase in the average time to withdrawal after oral administration of  
5 50 mg/kg or less in this model.

Example 18f

Sedation

10 Sedation may be determined using the method described by Fitzgerald et al., *Toxicology* 1988, 49(2-3)433-9. Preferred compounds of the invention do not produce reproducible or significant sedation at intravenous doses of less than 25 mg/kg (preferably less than 10 mg/kg) or at oral doses of less  
15 than 140 mg/kg (preferably less than 50 mg/kg).

(54) Title: CAPSAICIN RECEPTOR LIGANDS

(57) Abstract: Disclosed are diaryl piperazines and related compounds. These compounds are selective modulators of capsaicin receptors, including human capsaicin receptors, that are, therefore, useful in the treatment of a chronic and acute pain conditions, itch and urinary incontinence. Methods of treatment of such disorders and well as packaged pharmaceutical compositions are also provided. Compounds of the invention are also useful as probes for the localization of capsaicin receptors and as standards in assays for capsaicin receptor binding and capsaicin receptor mediated cation conductance. Methods of using the compounds in receptor localization studies are given.

## FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

Continuation of Box I.2

Claims Nos.: 186, 188, 189 (all partly)

Present claims 186, 188, 189 relate to a compound defined by reference to a desirable characteristic or property, namely that it is a high potency capsaicin receptor antagonist in an in vitro assay of capsaicin receptor antagonism (claims 186, 188, 189) and that it is not a capsaicin analog (claims 186, 189).

The claims cover all compounds having this characteristic or property, whereas the application provides support within the meaning of Article 6 PCT and/or disclosure within the meaning of Article 5 PCT for only a limited number of such compounds. In the present case, the claims so lack support, and the application so lacks disclosure, that a meaningful search over the whole of the claimed scope is impossible. Independent of the above reasoning, the claims also lack clarity (Article 6 PCT). An attempt is made to define the compounds by reference to a result to be achieved. Again, this lack of clarity in the present case is such as to render a meaningful search over the whole of the claimed scope impossible. Consequently, the search has been carried out for those parts of the claims which appear to be clear, supported and disclosed, namely those parts relating to the methods making use of compounds mentioned in claim 187, i.e. compounds covered by claims 1-176 and by the concrete examples given in the description (with regard to claims 186 and 188), and to the methods making use of compounds mentioned in claim 190, i.e. compounds covered by claim 50 and by the examples given in the description (with regard to claim 189).

The applicant's attention is drawn to the fact that claims, or parts of claims, relating to inventions in respect of which no international search report has been established need not be the subject of an international preliminary examination (Rule 66.1(e) PCT). The applicant is advised that the EPO policy when acting as an International Preliminary Examining Authority is normally not to carry out a preliminary examination on matter which has not been searched. This is the case irrespective of whether or not the claims are amended following receipt of the search report or during any Chapter II procedure.
